## Improved What3Words

Jane Harrigan

## Background: "What3Words"

Many places have no address or easily memorable location

• "What3Words" is a company which developed a global "addressing" system based on using three words to uniquely identify every 3m x 3m location on earth

• For example, the location of the STC is called "error.treating.movement"

### Limitations of "What 3 Words" approach

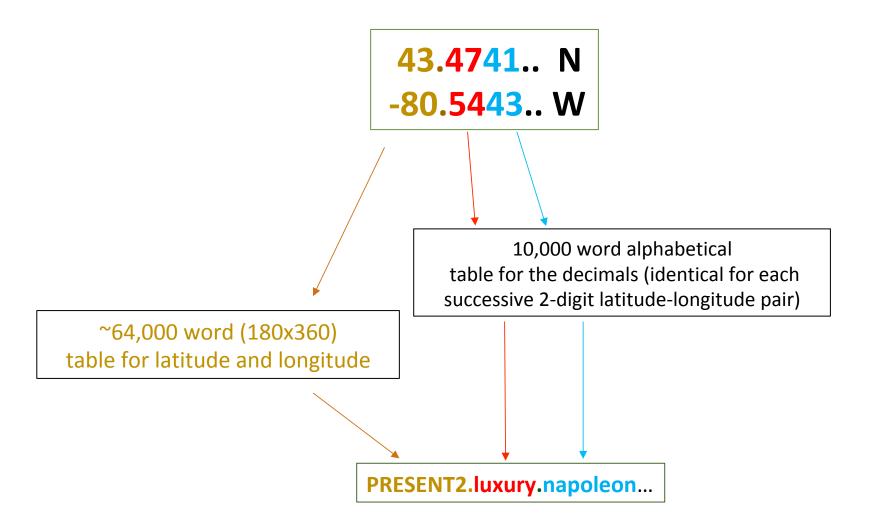

- Fixed precision always 3m x 3m
- Not hierarchical
- Secret algorithm
- Requires an app and internet to be useful
- Names give no clues for navigation
- Not translatable to any other location/addressing scheme

# Google "Plus Codes" encode a grid decreasing 20-fold with each digit

Alternatively, just the last 6 digits with a city and country:

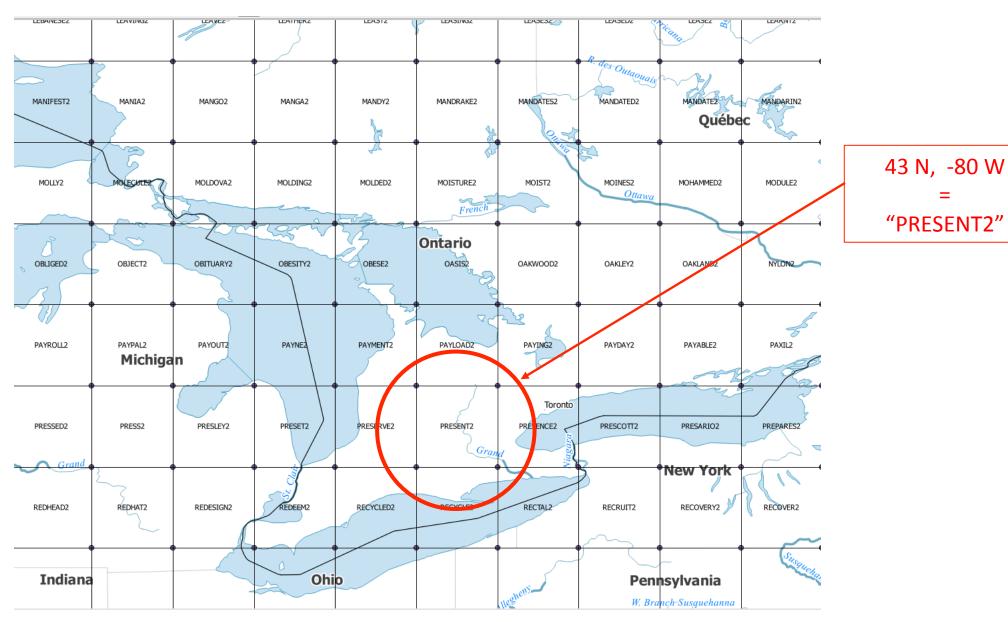

FFC4+9M, Waterloo, ON, CANADA is a Google "Plus Code

#### "Waterloo Naming System"

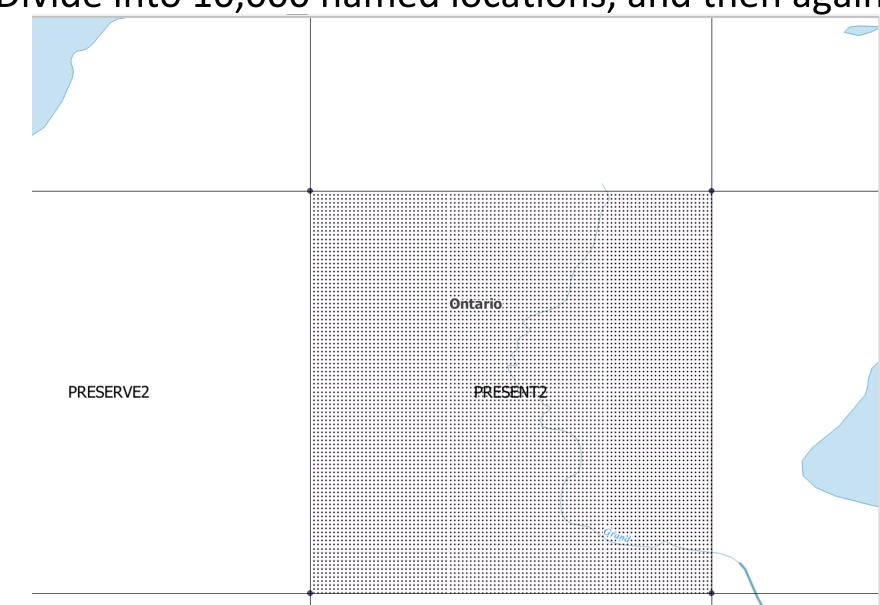

Lat	Long	Combo	Word			
00	00	00_00	zucchini			
00	01	00_01	zoological			
00	02	00_02	zoology			
00	03	00_03	z00			
00	04	00_04	zoning			
00	05	00_05	zones			
00	06	00_06	zombie			
41 43 41_43 napoleon						
••••						
47 54 47_54 luxury						

## Iterative naming example

Divide into 10,000 named locations, and then again

#### Our building

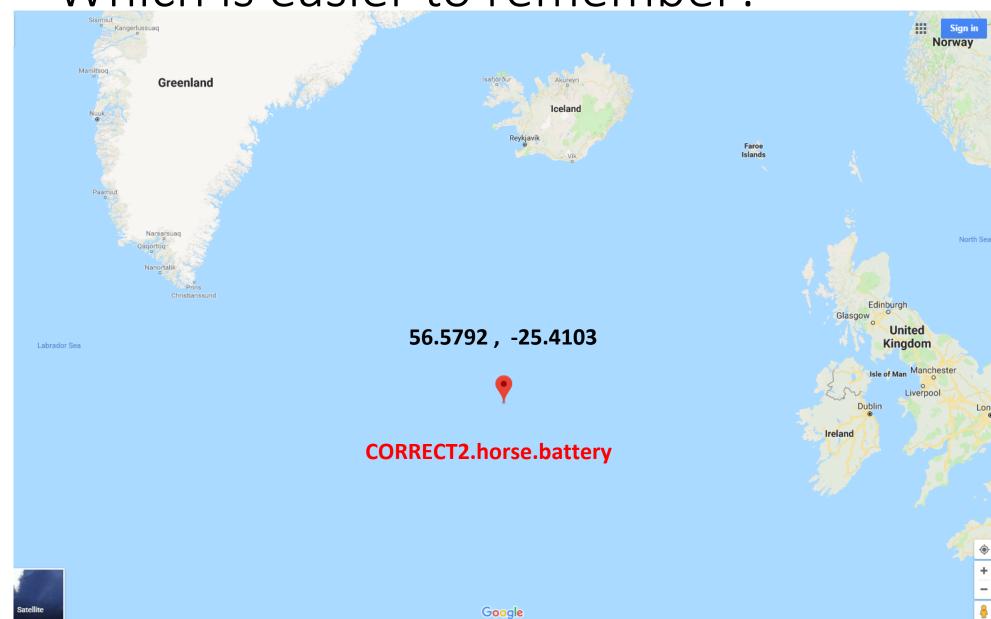

43.4741 N, -80.5443 W = "PRESENT2.luxury.napoleon"

# A systematic "human friendly" location naming system which is:

- hierarchical
- expandable to any resolution
- simple and public domain
- fits on a few pieces of paper
- globally unique and unchanging
- Very easily translatable to traditional location schemes

### Which is easier to remember?

## Acknowledgements

- Richard Harrigan
- Peter Deadman

## Google Plus codes are not really better than latitude and longitude

A complete "Open Location Code" like 86MXFFC4+9M is not useful for humans

Removing the 86MX and "Shortening" to FFC4+9M, Waterloo, Canada is still not very useful for humans, AND now this is not unique, requires a search to discover the complete location, and is subject to changes over time

The latitude and longitude **43.4709**, **-80.5433** are also not really useful for humans The google approach is equivalent to "shortening" the decimal latitude and longitude location by removing the starting digits 43, -80; leaving:

4709, 5433, Waterloo, ON, Canada

(or 45740393, Waterloo, ON, Canada)

The "Plus code" has saved only a single digit over just using the latitude and longitude - but at the expense of obfuscating the simplicity of latitude and longitude, AND being dependent on possible changes in political names and borders!

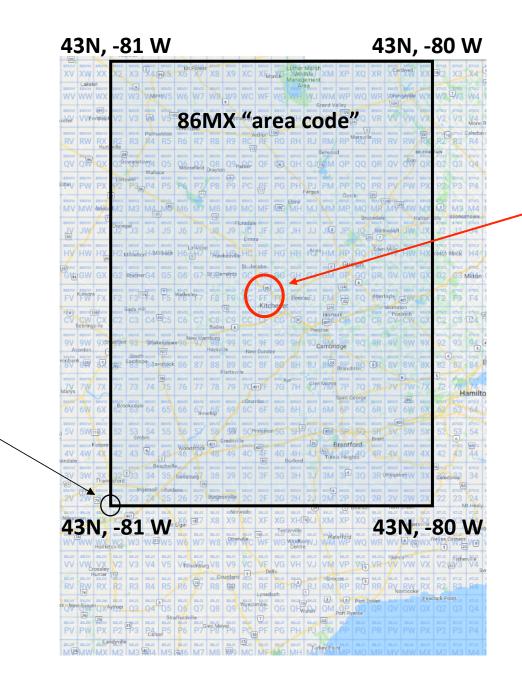

#### A fatal flaw in "Plus Codes"?

• In addition, referencing to the latitude and longitude grid nearest a given city (in this case, located at 43,-81) means the "Plus Codes" for

```
FFC4+9M, Waterloo, Canada, FFC4+9M, Kitchener, Canada, FFC4+9M, Guelph, Canada, FFC4+9M, Brantford, Canada
```

all refer to exactly the same physical place (!). This could be extremely confusing.

• One can only imagine the issues this leading digit truncation would cause, as cities are not unique. This seems like a terminal flaw in the Plus Code approach.

The

"Origin" (86

MX) is the

Waterloo,

Kitchener,

Brantford

Guelph,

and

same for

The FF section of "area code" 86MX is the same for Waterloo, Guelph, Kitchener and Brantford, so these Plus Codes all refer to exactly the same place:

FFC4+9M, Waterloo, Canada, FFC4+9M, Kitchener, Canada, FFC4+9M, Guelph, Canada, FFC4+9M, Brantford, Canada
